

Joshua Peek

A main challenge in designing loops is choosing between simplicity and flexibility. For example, adding only a 'while' loop is easy to implement since it just needs a condition and a body:

```
while (x < 5) {  
    x = x + 1;  
}
```

The compiler could translate this into pseudocode like:

```
L1: if (x >= 5) goto L2  
    x = x + 1  
    goto L1
```

But adding 'for' loops makes parsing harder because of the extra initialization and update parts. A simple solution is to translate 'for' loops into 'while' loops internally, which keeps the compiler cleaner while still offering more options for the programmer.
